

Abstract

A method and apparatus for generating a patient treatment plan includes
5 processing that begins by providing a list of health care services to a patient and/or care
provider. The processing continues by prompting for input of digital information
regarding the patient when health care services applicable to addressing the patient's
treatment needs have been concurrently selected. The processing continues by
determining whether a sufficient amount of digital information has been received. If so,
10 the processing continues by simulating treatment of a patient based on the digital
information, a treatment objective, and normalized patient data. The processing then
continues by generating the patient treatment plan in accordance with the simulating of
the treatment when the simulated treatment results have been acknowledged.
